What operations do we need to implement for dictionaries? I know it is going to be red-black tree implementation but do we need to insert, delete, search etc or we can just show you the tree structure after insertions.

What things are you going to check for dictionary? Please reply here as assignment description is not very clear, at least for me.

I talked to Dr. Lusth about it and I believe he said the only methods that we must implement are insert and get. No delete operations.

^ this is correct. You do not need to implement delete.

Your dictionary example code should show off inserts and gets.

Also, you can simulate delete a (key,value) by calling get with (key,obviously invalid value) whenever you need to.
