Does the curry function only need to be able to accept one argument to function "f" at a time (i.e. (curry f a)) or does it need to be able to accept any number of arguments (i.e. (curry f a b), (curry f a b c))? 

No, just one. A true ability to curry would accept a variable number of arguments, though.

Great, thank you!

after writing my curry function it is still returning a function not an answer. I am running the test script, any thoughts?

When you give the very last input, it should evaluate the function passed in with the parameters passed in. In other words don't return a new lambda, just evaluate.

How do I know it's the last one, is it always five args one function and four numbers?
Yessir.
