I had the precedence wrong in an example. The example should be:

```
$ calculon -d  
5 + 3 * ( 4 - 2 ) - 1 ;
5 3 4 2 - * 1 - +
$
```

I've updated the spec; refresh your web page.

---

Just to clarify since this seems to go against common thought, the correct precedence is exponentiation > modulus > divides > multiply > minus > plus correct?

---

Yes, life is harder with precedence. It's even harder with precedence levels, so I've made it a tad easier.

---

Will the last expression ever contain assignment? If so, is the correct result the value that was assigned? And how would we make a postfix expression with assignment?

---

Assignment is an operator. It will have the lowest precedence. And yes, the value assigned is the result of evaluating the expression.
