When are we supposed to know to stop reading expressions for a regular call to Calculon (where the user inputs themselves).

In this example, it runs 4 lines:

```
$ calculon
    var x = 1 ;
    var y = 2 ;
    x = x + y ;
    y = x + y ;
    5
```

In this example, it runs twice:

```
$ calculon
    var x = 3 ;
    x ;
    3
    $
```

Any suggestions?

Try catting a file to calculon:

cat mytestfile | calculon

If that works, you have done your keyboard input correctly.

Yes, does:

calculon mytestfile

work?
