I see from the first-round test results that pop and dequeue have two parameters, but on the assignment0 page it only displays them both as having a single parameter.

Pop only takes one parameter, a stack. Dequeue also only has one parameter, a queue. The test incorrectly states that it is popping or dequeuing from certain indexes; this is not the behavior or pop or dequeue.

Welp that's not how pop or queue is intended to work, and furthermore, it ran successfully on my program which takes the single parameters I described, so I think something about the test is false.

I also had pop and dequeue take in a single parameter and mine worked for most of the test.
That's an error in the test description.
