I am a little confused on setting the data type for the values. I understand how to find the data
type, but not quite sure where to put display or compare string/integer as a parameter. My biggest
concern is that my program will not function when my files are replaced. Does anyone have a
good understanding of this? Where should display or compare string/integer be a parameter?
Should newVBST take vbstValueDisplay or displayString?

A vbst holds the display and compare functions which are something like displayInteger,
displayString, etc. A vbst holds a pointer to a bst tree. That bst will hold display and compare
functions which you will pass in from vbst that you wrote which display the value of a vbstValue
and its associated properties. The vbstValue will hold display and compare functions which allow
you to operate on the value it holds, i.e. displayInteger or displayString.
